Metal Industry Indicators

Indicators of Domestic Primary Metals, Steel, Aluminum, and Copper Activity

February 2013

The primary metals leading index increased in January, and its relatively high 6-month smoothed growth rate points to a recovery in U.S. metals industry activity in 2013. Although the leading index growth rates have been negative for much of 2012, they have risen steadily since June. The U.S. economic recovery is supporting domestic primary metals industry activity with modest metals demand from the manufacturing sector and more so from the construction sector. However, slower global economic growth continues to reduce demand for U.S. metals. The metals price leading index ended 2012 with a sharp increase, suggesting that some metal prices could rise. The rate of growth of nonferrous metals inventories held in the United States has slowed, but the inventory levels continue to set new recent highs. Furthermore, rising global metals stocks are suppressing metal price growth.

The **primary metals leading index** increased 1.4% to 164.5 in January, from an upwardly revised 162.3 in December. The index's 6-month smoothed growth rate, a compound annual rate that measures the near-term trend increased to 5.3% from a revised 2.7% in December. A growth rate above +1.0% is usually a sign of an upward near-term trend for future metals activity, while a growth rate below -1.0% indicates a downward trend. For an explanation of these indexes and a definition of the primary metals industry, see page 10.

Three of the index's four available components increased in January, and one declined. A third consecutive monthly increase in the stock price index combining construction and farm machinery companies and industrial machinery companies contributed 1.0 percentage point to the net gain in the leading index. A surge in the Institute for Supply Management's PMI contributed 0.7 percentage points. It moved further in the range that denotes an expansion in future U.S. manufacturing activity. The rise in the USGS metals price index growth rate was so slight that its contribution rounded to zero. In contrast, a shorter average workweek in primary metals establishments held the leading index back 0.4 percentage points in January. The primary metals leading index will likely be revised next month when the remaining four components become available.

The relatively high primary metals leading index growth rate indicates that activity in the U.S. metals industry could increase in the near term. Although new orders for durable goods declined sharply in January, it is not yet suggesting a downward trend. The modest domestic metals consumption generated from the manufacturing sector will most likely be augmented by the more robust metals consumption in the U.S. housing industry. However, the global demand for U.S. metals continues to be restrained.

The **steel leading index** increased 1.3% in December, the latest month for which it is available, to 111.1 from a revised 109.7 in November. Its 6-month smoothed growth rate increased to 1.2% from a revised -1.3%. The rising inflation-adjusted M2 money supply growth rate accounted for half of the increase in the steel leading index. A longer average workweek and the rising steel scrap price growth rate also boosted the index. In contrast, decreased inflation-adjusted new orders for iron and steel mill products and fewer shipments of household appliances offset those gains. The steel leading index growth rate has generally moved higher since July and is suggesting that the decline in U.S. steel industry activity may have ended.

The **copper leading index** increased 1.3% in December to 127.5 from a revised 125.9 in November. Its 6-month smoothed growth rate increased to 6.1% from a revised 4.6% in November. Five of the index's six indicators posted gains in December and the contribution from the only decreasing one was negligible. A longer average workweek in nonferrous metals (except aluminum) establishments made the largest positive contribution to the copper leading index in December. Rising inflation-adjusted new orders for nonferrous metal products also made a sizable contribution. The price of copper slipped in December, and its negative contribution rounded to zero. The high copper leading index growth rate would normally suggest that activity in the U.S. copper industry could increase; however, ample copper inventories will likely restrain activity growth in the near future.

Growing Inventories Keep Metal Prices from Moving Up

The **metals price leading index** increased 1.2% in December, the latest month for which it is available, to 108.5 from a revised

U.S. Department of the Interior
U.S. Geological Survey

107.2 in November, and its 6-month smoothed growth rate increased to 2.6% from a revised 0.4% in November. All four of the leading index's indicators increased. The growth rate of the inflation-adjusted value of new orders for U.S. nonferrous metal products made the largest contribution to the overall increase in the leading index. It contributed 0.4 percentage points. Growth in new orders generally fell in 2012, but picked up in November and December. The growth rate of the trade-weighted average exchange value of other major currencies against the U.S. dollar contributed 0.3 percentage points. The Organization for Economic Cooperation and Development (OECD) Total Leading Index growth rate inched up a fourth consecutive month in December, indicating continued global economic weakness. Its contribution was 0.1 percentage point. The wider yield spread between the U.S. 10-year Treasury note and the federal funds rate also contributed 0.1 percentage point. The metals price leading

index signals major changes in the growth rate of nonferrous metal prices an average of 8 months in advance.

The growth rate of the inflation-adjusted value of U.S. nonferrous metal products inventories, which is an indicator of supply and usually moves inversely with the price of metals, decreased in December. However, these inventory levels continued to rise and now stand at a nearly 4-year high. High global metals inventories will likely keep metals prices from moving significantly higher until some of these stocks are reduced.

The business cycle and inventories are only two factors in metal price determination. Some other factors that affect prices include changes in metals production, strategic stockpiling, foreign exchange rates, speculation, and production costs.

Note: The components of the Leading Index of Metal Prices are the spread between the U.S. 10-year Treasury Note and the federal funds rate, and the 6-month smoothed growth rates of the deflated value of new orders for nonferrous metal products, the Organization for Economic Cooperation and Development (OECD) Total Leading Index, and the reciprocal of the trade-weighted average exchange value of the U.S. dollar against other major currencies. The Metal Industry Indicators (MII) Nonferrous Metals Price Index measures changes in end-of-the-month prices for primary aluminum, copper, lead, and zinc traded on the London Metal Exchange (LME). The steel scrap price used is the price of No. 1 heavy melting. Inventories consist of the deflated value of finished goods, work in progress, and raw materials for U.S.-produced nonferrous metal products (NAICS 3313, 3314, & 335929). Six-month smoothed growth rates are based on the ratio of the current month's index or price to its average over the preceding 12 months, expressed at a compound annual rate.

U.S. Geological Survey, February 2013

Explanation

Each month, the U.S. Geological Survey tracks the effects of the business cycle on five U.S. metal industries by calculating and publishing composite indexes of leading and coincident indicators. Wesley Mitchell and Arthur Burns originated the cyclical-indicators approach for the economy as a whole at the National Bureau of Economic Research in the mid-1930s. Over subsequent decades this approach was developed and refined, mostly at the National Bureau, under the leadership of Geoffrey H. Moore.[1]

A business cycle can briefly be described as growth in the level of economic activity followed by a decline succeeded by further growth. These alternating periods of growth and decline do not occur at regular intervals. Composite indexes, however, can help determine when highs and lows in the cycle might occur. A composite index combines cyclical indicators of diverse economic activity into one index, giving decision makers and economists a single measure of how changes in the business cycle are affecting economic activity.

The indicators in the metal industry leading indexes historically give signals several months in advance of major changes in a coincident index, a measure of current metal industry activity. Indicators that make up the leading indexes are, for the most part, measures of anticipations or new commitments to various economic activities that can affect the metal industries in the months ahead.

Composite coincident indexes for the metal industries consist of indicators for production, shipments, and total employee hours worked. As such, the coincident indexes can be regarded as measures of the economic health of the metal industries.

The metal industry coincident indexes reflect industry activity classified by the U.S. Standard Industrial Classification (SIC) and the North American Industry Classification System (NAICS). Of the five metal industries, primary metals (NAICS 331) is the broadest, containing 25 different metal processing industries. Steel, aluminum, and copper are specific industries within the primary metals group.

The SIC was the main vehicle used by the U.S. Government and others in reporting industry economic statistics throughout most of the last century. Starting with the 1997 U.S. Economic Census, the U.S. Government began using the NAICS, which classifies economic data for industries in Canada, Mexico, and the United States. In general, metal industry indexes starting in 1997 begin to reflect the NAICS classification, while indexes for earlier years follow the SIC. Hence, composite indexes from 1997 forward are not entirely consistent with those of earlier years.

The largest change to primary metals because of the NAICS deals with other communication and energy wire manufacturing (NAICS 335929). Under NAICS, this manufacturing has been removed from primary metals and added to electrical equipment, appliance, and component manufacturing. Because monthly shipments and new orders for this wire are not available, the USGS is estimating their values from 1997 onward and adding them to the appropriate metal industry indicators and indexes to maintain consistency.

---

[1]**Business Cycle Indicators, A monthly report from The Conference Board** (March 1996).

There are other small changes to the primary metals industry because of the switch to the NAICS. Coke oven activity not done by steel mills, for example, is removed and alumina refining, a part of industrial inorganic chemical manufacturing under the SIC, is added. Since the historic trends of the composite indexes are not affected by these small changes, the USGS is not making specific adjustments to the indexes for them for the periods before and after 1997.

The metal industry leading indexes turn before their respective coincident indexes an average of 8 months for primary metals and 7 months for steel and copper. The average lead time for the primary aluminum leading index is 6 to 8 months, and the average lead time for the aluminum mill products leading index is 6 months.

The leading index of metal prices, also published in the *Metal Industry Indicators*, is designed to signal changes in a composite index of prices for primary aluminum, copper, lead, and zinc traded on the London Metal Exchange. On average, this leading index indicates significant changes in price growth about 8 months in advance.

The growth rate used in the *Metal Industry Indicators* is a 6-month smoothed growth rate at a compound annual rate, calculated from a moving average. Moving averages smooth fluctuations in data over time so that trends can be observed. The 6-month smoothed growth rate is based upon the ratio of the latest monthly value to the preceding 12-month moving average.

$$\left[\left(\frac{current\ value}{preceding\ 12\text{-}month\ moving\ average}\right)^{\frac{12}{6.5}} - 1.0\right] * 100$$

Because the interval between midpoints of the current month and the preceding 12 months is 6.5 months, the ratio is raised to the 12/6.5 power to derive a compound annual rate.

The growth rates measure the near-term industry trends. They, along with other information about the metal industries and the world economy, are the main tools used to determine the outlook of the industries. A 6-month smoothed growth rate above +1.0% usually means increasing growth; a rate below –1.0% usually means declining growth.

The next update for these indexes is scheduled for release on the World Wide Web at 10:00 a.m. EDT, Friday, March 22. The address for *Metal Industry Indicators* on the World Wide Web is: http://minerals.usgs.gov/minerals/pubs/mii/
